STAT 640: Homework 8

Due Wednesday, March 30, 11:59pm MT on the course Canvas webpage. Please follow the homework guidelines on the syllabus.

Name: Hannah Butler

Problem 1

Researchers wish to study the effectiveness of different building materials for pig shelters. They obtain data on 9 pig farms, three that have shelters of straw, three that have shelters of wood, and three that have shelters of brick. For each farm, they have a measure of wolf attack severity, ranging from 0 (no attacks) to 10 (all pigs killed by wolves). The observed data, in the order of ("straw", "straw", "straw", "wood", "wood", "brick", "brick", "brick"), are:

```
Y <- cbind(9:1)
```

Define the categorical indicators

```
straw <- rep(c(1, 0), times=c(3, 6))
wood <- rep(c(0, 1, 0), each=3)
brick <- c(rep(0, 6), rep(1, 3))</pre>
```

a. Fit a linear model with no intercept and the predictors straw, wood, and brick—in that order (i.e., $lm(Y \sim 0 + straw + wood + brick)$). Construct the sum of squares (SS) and mean squares (MS) for a Sequential (Type I) ANOVA table using only basic matrix operations in R. Verify your numbers against anova().

Answer:

```
# design matrix
X <- cbind(straw, wood, brick)
# parameter estimates
bh <- solve( t(X)%*%X ) %*% (t(X)%*%Y); t(bh)

## straw wood brick
## [1,] 8 5 2

RSS <- t(Y - X%*%bh) %*% (Y - X%*%bh); RSS

## [,1]
## [1,] 6</pre>
```

Source	Estimate	Degrees of Freedom	Sum of Squares (I)	Mean Squares
Straw	8	1	192	192
Wood	5	1	75	75
Brick	2	1	12	12
Residuals	NA	6	6	1

```
# Type 1 SS: in order
P_0 \leftarrow diag(0, 9)
# straw / nothing else
P_x1 <- straw %*% solve(t(straw) %*% straw) %*% straw
SS_X1_0 \leftarrow t(Y) \%*\% (P_x1 - P_0) \%*\% Y
# wood | straw
X2 <- cbind(straw, wood)</pre>
P_x2 \leftarrow X2 \%  solve(t(X2)%*%X2) %*% t(X2)
SS_X2_X1 \leftarrow t(Y) \%*\% (P_x2 - P_x1) \%*\% Y
# brick | straw, wood
P_x3 \leftarrow X \%*\% solve(t(X)\%*\%X) \%*\% t(X)
SS_X3_X2 <- t(Y) %*% (P_x3 - P_x2) %*% Y
```

Because each group accounts for 1 degree of freedom, the MSE values will be the same: .

```
#check
pig_df <- data.frame(Y, X)</pre>
pig_lm <- lm(Y ~ 0 + straw + wood + brick)</pre>
anova(pig_lm)
## Analysis of Variance Table

```

b. Repeat (a) but now with an intercept and a different ordering: lm(Y ~ wood + brick + straw). Construct the sum of squares (SS) and mean squares (MS) for a Sequential (Type I) ANOVA table using only basic matrix operations in R. Verify your numbers against anova().

Answer: Since the design matrix X_{int} will no longer be one of full rank, we must use a generalized inverse to compute $\hat{\beta}$. This can be found by partitioning $X_{int} = \begin{bmatrix} 1 & X \end{bmatrix}$ and finding the generalized inverse as

$$G = \begin{bmatrix} \mathbf{0} & \mathbf{0} \\ \mathbf{0} & (\mathbf{X}^T \mathbf{X})^{-1} \end{bmatrix}$$

c. The ANOVA table in (b) looks strange. Explain why this happens.

Answer:

Problem 2

Consider the linear model $\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$ with $\boldsymbol{\epsilon} \sim N(0, \sigma^2 \mathbf{I}), \ \boldsymbol{\beta} = \begin{bmatrix} \beta_1 & \beta_2 & \beta_3 \end{bmatrix}^\mathsf{T}$ and design matrix:

$$m{X} = egin{bmatrix} 1 & 0 & 0 \ 1 & 0 & 0 \ 1 & 0 & 0 \ 0 & 1 & 0 \ 0 & 1 & 0 \ 0 & 1 & 0 \ 0 & 0 & 1 \ 0 & 0 & 1 \ 0 & 0 & 1 \end{bmatrix}.$$

Letting $J_n = \frac{1}{n} \mathbf{1}_n \mathbf{1}_n^\mathsf{T}$ and $\mathbf{0}_{j,k}$ be a $j \times k$ matrix of zeros, suppose we have the following projection matrices:

$$P_1 = \begin{bmatrix} J_3 & 0_{3,3} & 0_{3,3} \\ 0_{3,3} & 0_{3,3} & 0_{3,3} \\ 0_{3,3} & 0_{3,3} & 0_{3,3} \end{bmatrix} \qquad P_2 = \begin{bmatrix} 0_{3,3} & 0_{3,3} & 0_{3,3} \\ 0_{3,3} & J_3 & 0_{3,3} \\ 0_{3,3} & 0_{3,3} & 0_{3,3} \end{bmatrix} \qquad P_3 = \begin{bmatrix} 0_{3,3} & 0_{3,3} & 0_{3,3} \\ 0_{3,3} & 0_{3,3} & 0_{3,3} \\ 0_{3,3} & 0_{3,3} & 0_{3,3} \end{bmatrix} \qquad P_4 = \begin{bmatrix} J_3 & 0_{3,3} & 0_{3,3} & 0_{3,3} \\ 0_{3,3} & 0_{3,3} & 0_{3,3} \\ 0_{3,3} & 0_{3,3} & 0_{3,3} \end{bmatrix} \qquad P_5 = \begin{bmatrix} J_3 & 0_{3,3} & 0_{3,3} \\ 0_{3,3} & 0_{3,3} & 0_{3,3} \\ 0_{3,3} & 0_{3,3} & J_3 \end{bmatrix} \qquad P_6 = \begin{bmatrix} 0_{3,3} & 0_{3,3} & 0_{3,3} \\ 0_{3,3} & 0_{3,3} & J_3 \\ 0_{3,3} & 0_{3,3} & J_3 \end{bmatrix} \qquad P_8 = \begin{bmatrix} 0_{3,3} & 0_{3,6} \\ 0_{6,3} & J_6 \end{bmatrix}$$

For each of the following quantities ((a) through (f)), provide the following information:

- 1. Does this represent a valid F-statistic for an F-test? If yes, answer remaining questions; if no, explain why not and then skip remaining questions.
- 2. What are the null and alternative hypotheses being tested?
- 3. Does this F-statistic correspond to a GLRT? If no, why not?
- 4. Would this F-statistic appear in a Type I ANOVA Table?
- 5. Would this F-statistic appear in a Type III ANOVA Table?

$$\begin{aligned} &\text{a.} \quad \frac{\boldsymbol{Y}^\mathsf{T}(\boldsymbol{P}_4-\boldsymbol{P}_1)\boldsymbol{Y}/\mathsf{rank}(\boldsymbol{P}_4-\boldsymbol{P}_1)}{\boldsymbol{Y}^\mathsf{T}(\boldsymbol{I}-\boldsymbol{P}_4)\boldsymbol{Y}/\mathsf{rank}(\boldsymbol{I}-\boldsymbol{P}_4)} \\ &\text{b.} \quad \frac{\boldsymbol{Y}^\mathsf{T}(\boldsymbol{P}_4-\boldsymbol{P}_1)\boldsymbol{Y}/\mathsf{rank}(\boldsymbol{P}_4-\boldsymbol{P}_1)}{\boldsymbol{Y}^\mathsf{T}(\boldsymbol{I}-\boldsymbol{P}_7)\boldsymbol{Y}/\mathsf{rank}(\boldsymbol{I}-\boldsymbol{P}_7)} \end{aligned}$$

```
\begin{array}{l} \mathrm{c.} & \frac{Y^{\mathsf{T}}(P_7-P_5)Y/\mathsf{rank}(P_7-P_5)}{Y^{\mathsf{T}}(I-P_7)Y/\mathsf{rank}(I-P_7)} \\ \mathrm{d.} & \frac{Y^{\mathsf{T}}(P_3-P_2)Y/\mathsf{rank}(P_3-P_2)}{Y^{\mathsf{T}}(I-P_6)Y/\mathsf{rank}(I-P_6)} \\ \mathrm{e.} & \frac{Y^{\mathsf{T}}(P_6-P_8)Y/\mathsf{rank}(P_6-P_8)}{Y^{\mathsf{T}}(I-P_7)Y/\mathsf{rank}(I-P_7)} \\ \mathrm{f.} & \frac{Y^{\mathsf{T}}(P_7-P_8)Y/\mathsf{rank}(P_7-P_8)}{Y^{\mathsf{T}}(I-P_7)Y/\mathsf{rank}(I-P_7)} \end{array}
```

Answers:

Problem 3

From Montgomery, (1997): An experiment is conducted to assess the effect of cotton content (percent) on tensile strength of men's shirts. Five levels of cotton percentage are considered, with five shirts tested for strength at each level. The results are included in the following data:

Using basic matrix operations in R, conduct a complete model utility test, which is the GLRT of the full model $Y_{ij} = \mu + \alpha_i + \epsilon_{ij}$, i = 1, ..., 5 versus the intercept-only reduced model, $Y_{ij} = \mu + \epsilon_{ij}$. Your answer should reproduce each value in:

```
fit<- lm(strength ~ factor(cotton))
anova(fit)</pre>
```

```
## Analysis of Variance Table
##
## Response: strength
## Df Sum Sq Mean Sq F value Pr(>F)
## factor(cotton) 4 475.76 118.94 14.757 9.128e-06 ***
## Residuals 20 161.20 8.06
## ---
## Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 ' ' 1
```
